

## Exercise 10.1

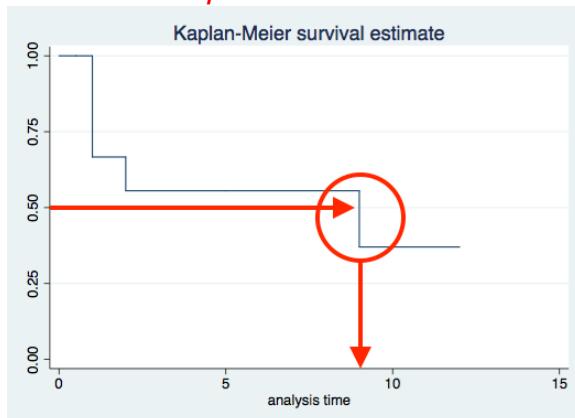

The survival times (in months) for 10 AIDS patients are as follows (\*=censored):

0.5\*, 1, 1, 1, 2, 5\*, 8\*, 9, 10\*, 12\*

- (a) A Kaplan-Meier curve was generated for these data using Stata. Use this to estimate the median survival time.

*First time where the curve dips below 0.5 is just before 10 months; from the data we see this must be the 9 month data point – so the median survival time is 9 months.*

The estimated survival function was obtained in Stata.

. sts list						
failure _d: died analysis time _t: months						
Time	Beg. Total	Net Fail	Lost	Survivor Function	Std. Error	[95% Conf. Int.]
.5	10	0	1	1.0000	.	.
1	9	3	0	0.6667	0.1571	0.2817 0.8783
2	6	1	0	0.5556	0.1656	0.2042 0.8045
5	5	0	1	0.5556	0.1656	0.2042 0.8045
8	4	0	1	0.5556	0.1656	0.2042 0.8045
9	3	1	0	0.3704	0.1872	0.0677 0.6933
10	2	0	1	0.3704	0.1872	0.0677 0.6933
12	1	0	1	0.3704	0.1872	0.0677 0.6933

(b) What is the estimated survival probability at 1 month? At 5 months? At 6 months?

1 month:  $\hat{S}(1) = 0.6667$

5 months:  $\hat{S}(5) = 0.5556$

6 months:  $\hat{S}(6) = 0.5556$

(c) Use the Stata output to confirm your answer to (a).

First value of  $\hat{S}(t)$  that is less than 0.5 is 0.3704, which first occurs at time = 9  $\rightarrow$  median survival is 9 months.

## Exercise 10.2

An observational study of mortality (time to death) for breast cancer patients was conducted. Patients were classified into two groups based on their tumor's immunohistochemical response (0=negative; 1=positive). Time to death or censoring was recorded in months.

The survival function estimate was separately for each group and a Kaplan-Meier plot created. A logrank test was also conducted. Stata output is on the next few pages. Use that output to answer the following questions.

- (a) What is the estimated 25th percentile of survival for each group? Interpret these quantities.

*Negative: 25th percentile = 56 months*

*→ We estimate that 25% of patients with negative tumors will survive less than 56 months.*

*Positive: 25th percentile = 38 months*

*→ We estimate that 25% of patients with positive tumors will survive less than 38 months.*

- (b) What is the estimated survival probability for each group at 2 years (24 months)? At 5 years (60 months)?

*Negative: 97.22% survival at 2 years; 72.22% survival at 5 years*

*Positive: 77.78% survival at 2 years; 55.56% survival at 5 years*

- (c) What are the null and alternative hypotheses for the logrank test that was performed? Write down the hypotheses using symbols, and also explain in words what the null and alternative hypotheses mean.

*Let  $S_0(t)$  = survival function for negative group;  $S_1(t)$  = survival function for the positive group*

*$H_0 : S_0(t) = S_1(t)$  → the two survival functions are identical (same/overlap at all time points)*

*$H_a : S_0(t) \neq S_1(t)$  → they differ at at least one time point*

(d) Report the p-value for the logrank test and write a one-sentence conclusion (in context). (Assume  $\alpha = 0.05$ .)

*p-value = 0.0191*

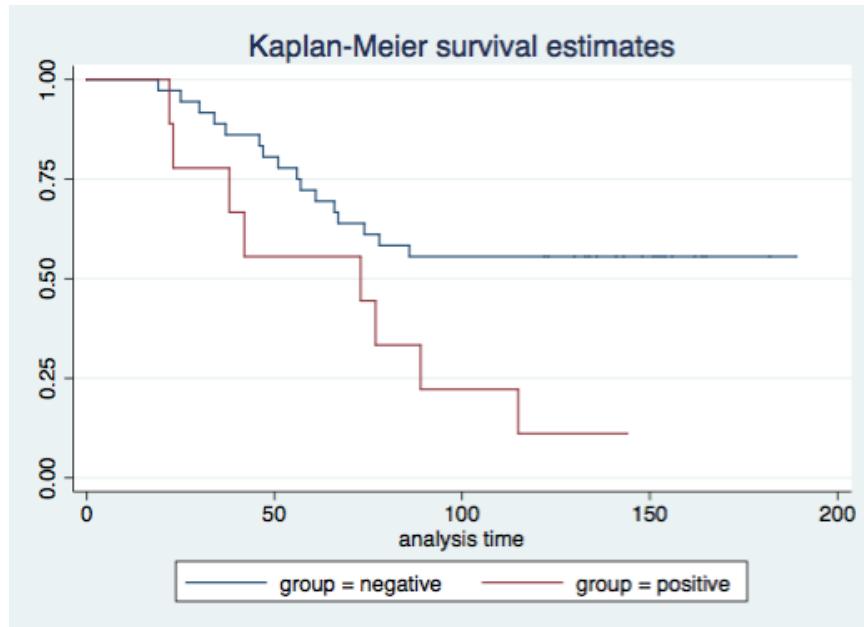

*There is evidence that survival (time to death) differs between patients with negative and positive tumors.*

```
. sts test group, logrank

Log-rank test for equality of survivor functions

          |   Events           Events
group    |   observed      expected
-----+-----
negative |       16        20.19
positive |        8         3.81
-----+-----
Total     |       24        24.00

chi2(1) =      5.49
Pr>chi2 =    0.0191
```

### Exercise 10.3

An observational study of survival of patients with cancer of the larynx was conducted. There were a total of 90 patients in the study, and for each patient we have information on the stage of cancer he/she has (stage = 1, 2, 3, 4). We also have the time in months until the patient died, was lost to follow-up, or was censored.

- (a) Below is a Kaplan-Meier plot of these data. Describe what you see in terms of how survival might differ by cancer stage. (Which one has the “best” survival? Which one the “worst”? ) Remember that you’re not doing a test – just describing what you see.

*In general, patients with higher cancer stage have worse survival – they die sooner. Patients with stage 4 cancer have the worst survival, followed by patients with stage 3 cancer. There doesn't appear to be much difference between stages 1 and 2, but both have better survival than stages 3 and 4.*

(b) Using the plot, roughly approximate the median survival for each group.

*Stage 1: 6.5 months; Stage 2: 7 months; Stage 3: 5 months; Stage 4: 1.5 months*

(c) A logrank test was conducted; output is below. Write a one-sentence summary of the test result (in context), including reference to a p-value. (Assume  $\alpha = 0.05$ .)

```
. sts test stage, logrank

Log-rank test for equality of survivor functions

      |   Events       Events
stage |   observed     expected
-----+
1    |        15      22.57
2    |         7      10.01
3    |        17      14.08
4    |        11      3.34
-----+
Total |        50      50.00

chi2(3) =      22.76
Pr>chi2 =    0.0000
```

*There is evidence that the survival (time to death) is not the same for all cancer stages ( $p < 0.00005$ ).*

*Note that we cannot definitively say which group(s) are significantly different from which other groups based on this test (would need additional tests – kind of like pairwise tests after an ANOVA).*
